Current Reporting Standards: recent review

Objective: to review reporting standards associated with HSUs used in recently published (2015-2018) cost-effectiveness analyses using case-study in cardiovascular disease

Current approaches to reporting HSUs used in models

- No literature review (too many hits, too much effort, no-one else does)
- Use outdated evidence (or just cite a value used in previous NICE submission)
- Don't cite original source (requires a detective to identify actual source: 3/4 iterations)
- Don't report actual values used (just cite any study & let reader find them if they really want to)
- Never, ever provide details of source study (e.g. patient characteristics, measure used, sample size etc.)
- 'Tweak' the values (several times)

www.ispor.org

Current approaches to reporting HSUs used in models

- Assume comparator has no benefit (equivalent to baseline of full health)
- Ignore adverse events (or make something up, or use evidence from a different treatment)
- Add clinical effects together when using two interventions, or ignore one (equivalent to using additive or minimum method to combine HSUs for concurrent events)
- Combine effects measured using different units (e.g. mmol/L & mg/dL) (equivalent to using SF-6D, HUI & EQ-5D within same model)
- Don't bother using the values in the report in the cost-effectiveness model

www.ispor.org

Overview of session

Presentations

- 2. Synthesis of health state utilities
- 3. Using health state utilities in costeffectiveness models
- 4. Minimum reporting standards The SpRUCE checklist

Discussion

SECTION

Searching, Identifying & Reviewing HSU for Use in CE Models

Andrew Lloyd DPhil Acaster Lloyd Consulting Ltd.

www.ispor.org

A working example – C/E analysis in cardiovascular disease

- Examined HSUs used in recently published (2015-2018) CE models
- Also examined the reporting standards from studies included in the review
- How thorough, transparent and reliable was reporting of values from literature?

9

www.ispor.org

Current Reporting Standards: Cardiovascular disease example

- 1/24 reported undertook literature review (limited details),
 1 other referred to this review for their evidence
- 6/24 referenced original sources for all HSUs
 - 18/24 referenced previous CE studies (as opposed to original sources)
 - 7/24 required at least 3 iterations to track down original sources
 - 13/24 used at least some HSU collected in 1990s (studies all published after 2014)

Ara R et al., Are current reporting standards used to describe health state utilities used in cost-effectiveness models satisfactory? Does this matter? Unpublished manuscript

Current Reporting Standards: Cardiovascular disease example

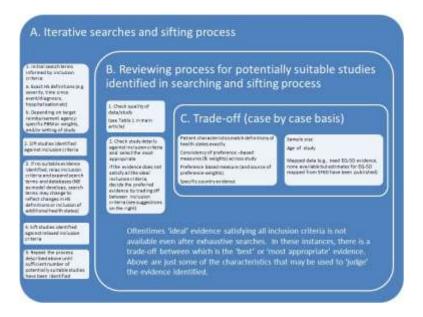

- 4/24 correctly reported all HSUs when checked against original sources
- 20/24 at least some HSUs could not be matched in references or original sources, or original sources could not be identified due to incorrect referencing
- 0/24 provided all basic details of sources (e.g. study type, sample size, age, details of health condition, time of data collection etc.)

Ara R et al., Are current reporting standards used to describe health state utilities used in cost-effectiveness models satisfactory? Does this matter? Unpublished manuscript

www.ispor.org

 Often HSU identification and selection is not a straightforward process.

Searching

- Wide range of sources may be appropriate
 - Clinical trials
 - Observational studies
 - Registries
 - Surveys
 - Previous economic evaluations
- Methods must accommodate
 - Needs of the model
 - Needs of the decision maker

13

www.ispor.org

Model development

- Model development often proceeds in an iterative fashion.
- Searching & identifying utilities is similar, the scope may change as model develops
 - Modeller and information specialist must work together closely.
- Initial focused searches may be broadened in later iterations.

Scope of searches

- Evidence relevant to a model
- All health states and aspects of treatment and management that might impact on health-related quality of life (HRQL)
 e.g. prophylactic treatments must include possible events in the future
- Different to standard SR approach
 - Standard SR approach Population Intervention Comparison Outcomes (PICO)
 - Focus here more constrained by model needs

15

www.ispor.org

Search scope

- Searches should consider:
 - · Health state descriptions within the model
 - Treatment effects of interventions and comparators of interest (treatment benefits and adverse effects)
 - Treatment effects and management at all stages of the clinical pathway included in the model
 - Carer utilities
 - Comorbidities
 - Concurrent clinical events/sequelae
 - General population norms
 - Moderators that might affect quality of life e.g., method of administration, treatment setting

Considerations when searching

- Exhaustive searching for every parameter is not efficient.
- Which states drive model results?
 - Focus resources here
 - Value of information (VOI) could inform when to stop searching*.
- Transparency
 - Not cherry picking
- * ISPOR publishing 2 VOI Good Practices Task Force Reports in August issue of Value in Health.

17

www.ispor.org

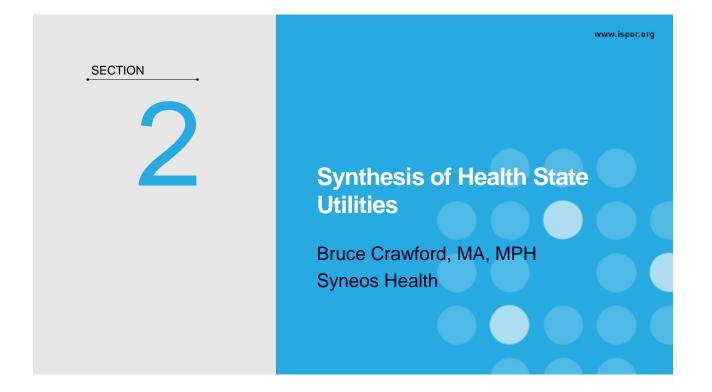

Reviewing

- Study population matches model?
- Sample size/ response rates/ loss to follow up/ missing data
- Proximity of data collection to event?
- Appropriateness of the measure (e.g. EQ-5D etc)
- Any evidence that the measure is inappropriate for disease area?

Selection

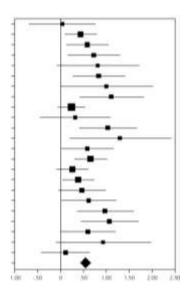

- Standardisation
 - Same measure used for all states in a model.
 - May be better to prefer a source study that describes more of the required health states.
 - But maintain minimum standards
- May require a trade off between different issues
- Selection rationale must be documented.

Why undertake synthesis?

- Often multiple published values for a given health state.
- Want to use all available evidence
- Synthesis should generate a more accurate estimate of the mean value and uncertainty and improve generalizability.

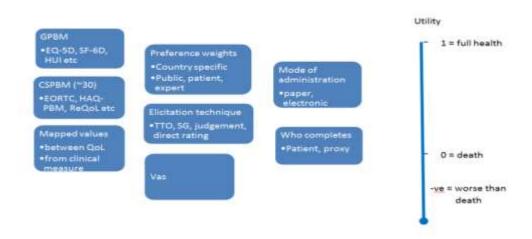

21

www.ispor.org

Measures and methods used to quantify utility

Should we undertake HSU synthesis?

- Difference in HSUs instruments / methods
- General preference based measures / condition-specific preference based measures
- Techniques used to elicit weights differ
- Mode of collection may differ
- Who completes the questionnaires proxy, patient, general public, clinician
- Preference weights
- Statistical techniques

23

www.ispor.org

EQ-5D-5L differences by country value set

- Different value sets on the same data produce significantly different results.
- Authors conclude that different country value sets are not interchangeable.

Table 3 EQ-5D-5L utility scores derived from Chinese, Japanese, Korean, and UK tariffs

Tariffs	n	Mean	Standard	Median	Minimum	Maximum
			deviation			
Chinese	608	0.828	0.184	0.879	-0.297	1.000
Japanese	608	0.802	0.164	0.823	0.062	1.000
Korean	608	0.831	0.137	0.829	0.010	1.000
UK	608	0.838	0.154	0.866	-0.213	1.000

Note: The difference among the four national tariffs was statistically significant $(z^2=438.952, P<0.001)$.

Abbreviation: EQ-5D-5L, five-level EuroQol-5 dimensions.

Different measures can produce vastly different results

Table 3. Comparison of Health State Utility Scores by Medical and Socioeconomic Factors

	Health State Utility Score by Measurement Method				
Variable (No. of Cases)	SG	TTO	VAS	EQ-5D	HUI3
Surgery type					-
Primary (n = 54)	0.93 (0.17)	0.95 (0.13)	0.76 (0.20) ^a	0.83 (0.19)2	0.78 (0.22)
Salvage (n = 5)	0.98 (0.04)	0.98 (0.04)	0.48 (0.13)3	0.62 (0.17) ²	0.37 (0.29)
Chemotherapy					
Yes (n = 13)	0.92 (0.10)	0.99 (0.03)	0.66 (0.19)b	0.76 (0.17)b,c	0.57 (0.38)
No (n = 87)	0.91 (0.18)	0.94 (0.14)	0.77 (0.18) ^b	0.83 (0.18)b,c	0.78 (0.21)
Oral cavity tumor stage				<u> </u>	
T1 or T2 (n = 47)	0.95 (0.13) ^a	0.96 (0.09)	0.77 (0.1%)	0.83 (0.18)	0.8 (0.21)
T3 or T4 (n = 20)	0.87 (0.22) ^a	0.88 (0.21)	0.7 (8.29)	0.83 (0.09)	0.74 (0.21)
Tracheotomy and/or feeding tube					
Yes (n = 6)	0.99 (0.02)	0.91 (0.12)	0.69 (0.23)	0.78 (0.14)	0.73 (0.25)
No (n = 94)	0.91 (0.17)	0.95 (0.14)	9 76 (0.19)	0.82 (0.18)	0.75 (0.29)

0.07 vs 0.21 diff in utility

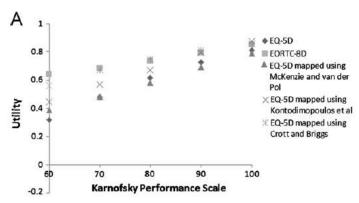

Noel et al. JAMA Otolaryngol Head Neck Surg 2015; 141(8): 696-703

www.ispor.org

Different mapping methods produce varied utilities for the same performance level

 Models may utilize functional levels such as HAQ DI levels of KPS levels, but the utility value assigned to that level can vary widely depending on the method used for utility

Rowen et al. ViH 2012; 15: 1059-1068

When undertake synthesis?

- Are there enough HSU estimates?
- Are studies sufficiently homogeneous?
- Are they using the same HSUV measurement system?

27

www.ispor.org

Methods of synthesis of HSUs

- Apply strict eligibility criteria to reduce heterogeneity
 - Same measurement instrument used
 - Same patient group (e.g., mild, moderate, severe depression; same KPS or HAQ-DI range)
- Strict eligibility is useful, but considerable heterogeneity often remains.
- Often there are not enough studies to restrict to a single measurement instrument.
- Use meta-regression
 - · Limited to parameters reported in each manuscript
 - It has been suggested that 10 studies per covariate should be used, but this is often not feasible.

Conclusions

- Currently, formal synthesis is very limited for HSUs due to heterogeneity of valuation methods, country differences, population differences, etc.
- Research still needed for methods of meta-regression in HSUV synthesis and when appropriate
- When conducting synthesis:
 - Limit to a single measure if possible; converting / mapping to a single measure may be useful, but be aware of the additional variance introduced.
 - Carefully evaluate heterogeneity and model the impact if using meta-regression.

29

SECTION Using Health State Utilities in Cost-effectiveness Models Prof John Brazier University of Sheffield

Identifying the most appropriate health state utility (HSU) is just the beginning

Issue	Recommendation	
Sensitivity analysis (SA)	Always begin with SA	
Discrete health states or discrete event simulation		
Individual mean HSUs or function-based HSUs		
Comorbidities & age		
Concurrent clinical events or conditions		
Treatment related adverse effects		
Acute clinical events		
Sensitivity analyses (again)	Always end with SA	

31

www.ispor.org

Begin: sensitivity analysis

- Look at the effect of each health state in model individually to inform level of literature searches.
- Which HSUs influence the ICER?
- Communicate with search/review team which HSUs really matter.

Model health states

- Decide the format of the model in terms of numbers and types of health states that differ according to HSU
 - Use clinical expertise & availability of evidence to inform decision
- If simple model structure implemented that may not represent all important HSUs
 - Examine & discuss expected effects of such omissions

33

www.ispor.org

Individual HSUs or function based: Clinical events – acute? chronic? fluctuating? progressive?

Simple 'acute' events:

- Bone fractures (e.g. hip, wrist, vertebrae)
- CVD (e.g. MI, angina, stroke)

Less obvious in chronic progress conditions:

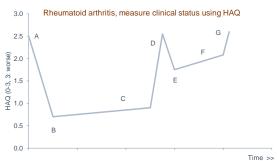

- Arthritic conditions 'flares'
- Asthma exacerbations (hospitalised?)
- Crohn's disease
- Age related macular degeneration

Consider:

- Frequency of events
- Severity of effect on QoL
- Duration of time effect lasts
- · 'Rebound' HSU after recovery
- Timing of data collection matches acute period of event?
- Explore likely effect if collection time does not match event

Discrete mean HSUs, or function based HSUs

A, Baseline HAQ=2.5, QoL=0.3, Start Tx1,

HAQ & QoL improve

B, HAQ & QoL improve

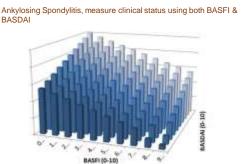

C, HAQ progression on Tx1

D, Stop Tx1, HAQ rebounds E, Start Tx2, HAQ & QoL improve

F, HAQ progression on Tx2

G, Stop Tx2, HAQ rebounds

RA: HAQ strong relationship with utility. Could use 3-30 discrete HS, depending on sample size for subgroups.

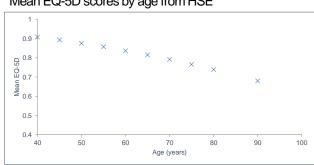

AS: Both BASDAI & BASFI have strong relationship with utility. 3-D matrix, substantial sample size read. Use function to predict utility conditional on BASDAI & BASFI (plus age, gender

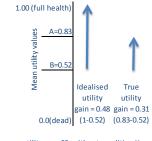

www.ispor.org

Comorbidities, age & role of general population norms (i.e. Baseline HSUs vary over model lifetime horizon)

Mean EQ-5D scores by age from HSE

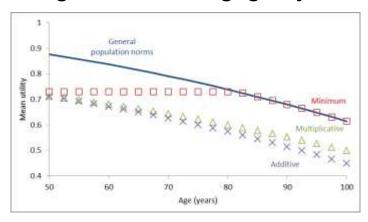

A: mean utility, age 69, without condition X B: mean utility, age 69, with condition X

Mean HSU is never equal to full health irrespective of measure, preference weights, age, condition or sample. Baseline of full health overestimates effects of avoiding events or conditions.

Combining HSUs when using age-adjusted baseline.

NB. For multiplicative DO NOT multiply HSUs together! Estimate 'multiplier' = observed mean HSU / baseline mean HSU (at age of sample).

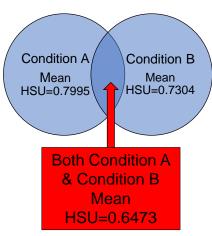

37

www.ispor.org

Concurrent clinical events or conditions

Ideally collect evidence from persons of interest

Only have mean HSUs from samples with just one of conditions (condition A, or condition B).

Estimate the HSU for the concurrent health state using HSU from Condition A, and Condition B:

Additive	=0.5903
Multiplicative	=0.6215
Minimum	=0.7304

It is recommended that the multiplicative method is used.

Treatment related adverse events (AE)

CONSIDER:

- Are AEs prevalent?
- Do treatment related AEs have substantial effect on QoL?
 - Check potential effect on ICER using SA in model.
- Is effect captured in evidence used for HSUs in model?
 - Those experiencing AE less likely to complete QoL measure.
 - · Take care not to double count effect if using trial data
- · What is likely duration of effect?
 - Chronic long term/ discrete short term & treatment withdrawal.
- TEST extreme values in model.

www.ispor.org

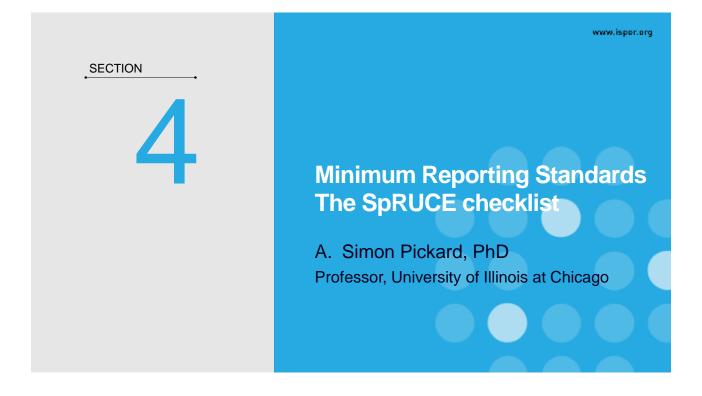

End: sensitivity analysis (again)

- ALL HSU represented by parametric probability distributions.
- Sample random values for PsA using Beta: rescale if –ve values possible
- Consistency: for ordered values, sample using 'difference method' [Ren 2017]
- Univariate: Test which HSUs influence ICER using Cls.
- Multi-variate: Test LCI & UCI that move ICER in same direction.

Recommendations when using health state utilities in models

Issue	Recommendation
Sensitivity analysis	Use to determine which HSUs influence the ICER & report these analysis if applicable.
Discrete health states	Expected effects of excluding potentially relevant HSUs from a cost-effectiveness model structure should be examined & discussed.
Individual mean HSUs or function-based HSUs	Relevance of data (e.g. study population, utility measures, alignment with model's health states) Reliability of analyses (e.g. precision of mean HSUs, validity of estimated utility functions) see Wailoo et al ISPOR TF
Comorbidities & age (baseline)	Mean HSU values represent comorbidity utility effects at the mean age of the utility study population. Age- specific comorbidity effects should be estimated using age-specific population norms.
Concurrent clinical events or conditions	The multiplicative method should be used to handle the utility effects of concurrent clinical events.
Treatment related adverse effects	Assess the extent utility effects of AEs are captured by the utility data used to estimate a model's non-adverse event . If AE HSUs are required, the range of HSUs required should be informed by expected effect on ICER.
Acute clinical events	In the absence of data collected around the event, plausible HSUs for the direct effects of acute events should be multiplied by the expected duration to assess the sensitivity of ICER to these utility effects.
Sensitivity analyses (again)	One way & multi-way SA of HSU, Beta (scaled) distributions. Difference method to account for ordering in PsA.

Current approaches to reporting HSUs used in models

- No literature review (too many hits, too much effort, no-one else does)
- Use outdated evidence (or cite a value used in previous NICE submission)
- Don't cite original source (requires a detective to identify actual source: 3/4 iterations)
- Don't report actual values used (just cite any study & let reader find them if they really want to)

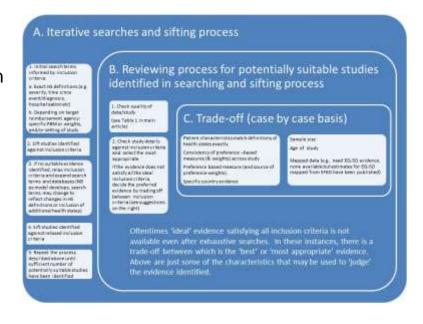

- 'Tweak' the values (several times)
- Assume comparator has no benefit (equivalent to baseline of full health)
- Ignore adverse events (or make something up, or use evidence from a different treatment)
- Add clinical effects together when using two interventions, or ignore one (equivalent to using additive or minimum method to combine HSUs for concurrent events)
- Combine effects measured using different units (e.g. SF-6D, HUI & EQ-5D within same model)
- Don't bother using the values in the report in the cost-effectiveness model

www.ispor.org

- HSU identification and selection is often not a straightforward process
 - Challenges to being explicit
 - Iterative search and sifting process

SpRUCE Checklist

- Provides minimum reporting standards for the <u>S</u>ystematic <u>R</u>eview of <u>U</u>tilities for <u>C</u>ost-<u>E</u>ffectiveness (SpRUCE checklist).
- Criteria intended to help model reviewers identify if HSU selection for the model was transparent and appropriate.
- A greater level of detail is likely needed to proceed to peerreviewed publication of a systematic review.
 - · Five sections:
 - 1. search strategy
 - 2. review process
 - 3. data extracted from each study
 - 4. basis for obtaining the final HSU
 - 5. use in cost-effectiveness models

45

www.ispor.org

SpRUCE Checklist: Search Strategy

Search terms and scope The final search strategy should be adequately defined and appropriate databases included in the search. Study selection criteria Explicit criteria for study identification/inclusion should be described and applied, such as patient group of interest, relevant age range and stage of disease/severity etc.

SpRUCE Checklist – Review Process

Review Process		
Quality check	Quality criteria for reviewing studies explicitly stated and applied.	
Assessment of relevance	Relevance of HSUs to model and target reimbursement agency described.	

47

www.ispor.org

SpRUCE Checklist: Key Data Extraction

Data Extracted (reporting of variables)		
Population/patient characteristics	Relevant patient characteristics (e.g. age, sex, comorbidities, diagnosis, severity of condition).	
Measure used to describe the HSUs	The measure used to obtain the HSUs.	
Valuation technique for preference weights	The technique used to value the heath state (e.g. TTO, SG), and the country (provide reference).	
Descriptive statistics of HSUs	The mean and variance around any HSU used in the model.	
Response rates to the measure used*	Report if response rates are likely to be a threat to validity.	
Loss to follow-up/ missing data*	Loss to follow-up (e.g. 1 year after fracture) and missing data should be reported, especially if they may threaten the representativeness of the HSUs.	
Original reference	The original source for the HSUs should be referenced (not a previous economic study that has used the evidence).	

SpRUCE Checklist

Selection/estimation of final health state value		
Basis for selecting HSUs	The rationale for selecting the HSUs used in the model should be justified.	
Method used to combine estimates	Where HSUs are combined, the analytic methods should be described e.g. meta-analysis.	

49

www.ispor.org

SpRUCE Checklist

Methods used when applying the health state		
utilities in model		
Actual HSUs	Report all actual HSUs used in the	
used	model together with associated	
	measure.	
Adjustments	Clearly describe any adjustments or	
or	assumptions relating to the use of	
assumptions	HSUs in the model, reporting both the	
	raw and final values used with worked	
	examples if required to clarify the	
	method used to adjust the data.
