Validated case-identifying algorithms using Canadian administrative health data: a targeted literature review

Bowie AC,¹ Tinajero MG,¹ Qian C¹ ¹Broadstreet HEOR, Vancouver BC Canada

Background

- Case-identifying algorithms are essential for identifying patients and events in real-world evidence studies
- Few centralized resources exist to support the implementation of case-identifying algorithms
- Single-payer health care systems in Canada provide comprehensive, population-level data to support the development and validation of algorithms

Objective

To identify and summarize published, validated case-identifying algorithms developed using Canadian administrative health data

Methods

- A targeted literature review (TLR) was conducted in Ovid MEDLINE, PubMed, and publications lists of Canadian administrative health databases
- English-language studies were included if they used Canadian data and reported ≥ 1 of the following performance measures: sensitivity (SE), specificity (SP), positive predictive value (PPV), or negative predictive value (NPV)
- No date restrictions were applied
- Three independent reviewers screened all identified abstracts and extracted study and algorithm details from eligible studies
- Studies were categorized by individual disease and disease areas based on the International Classification of Diseases (ICD)-10 classification system

Abbreviations: CKD, chronic kidney disease; eGFR, estimated glomerular filtration rate; ICD-10, International Classification of Diseases - 10th Revision; NPV, negative predictive value; PPV, positive predictive value; RWE, real world evidence; SE, sensitivity; SP, specificity; TLR, targeted literature review

studies were identified, and 82 eligible studies reporting 1453 algorithms were summarized ne 82 studies, 48 (58.5%) used data from the most populous province of **Ontario** onic kidney disease, diabetes, hypertension, and rheumatoid arthritis were the most frequent areas of focus (each representing ~4% of included studies)

	n (%)	Availability of porformance estimates	Algorithms		
of diseases with ≥ 1 algorithm (n = 82)	71 (86.6%)	Availability of performance estimates	n = 1453	Figu	
of ICD-10 chapters with ≥ 1 algorithm	15 (75%)	Any performance measure, n (%)	1453 (100%)	each

Future applications

2. Example of database layout

	Algorithm components				Performance						
or r)	Disease	Diagnosis	Findings	Procedures	Medication	Description	SE	SP	PPV	NPV	Gold standard
013)	CKD	ICD-10: N18	No	No	No	≥ 1 hospital discharge OR ≥ 1 physician claim in 5-years	12.24	99.45	80.08	86.17	eGFR <45 mL/min per 1.73 m2

3. Flowchart of living database lifecycle and application

Results

Performance estimates will be summarized to *facilitate* comparisons between algorithms and support algorithm selection for application in RWE studies

Identification of validated algorithms for use in RWE research

Published literature

Publication of validated algorithms

BROADSTREET HEALTH ECONOMICS & OUTCOMES RESEARCH

Limitations

Generalizability of the summarized algorithms beyond the Canadian context may require additional validation due to region-specific variations in coding

Conclusions

- This study showed good coverage of Canadian-specific case identifying algorithms, with at least one algorithm identified for most ICD-10 chapters
- Limited resources to support the identification and application of caseidentifying algorithms exist
- To support validity and efficiency in RWE evidence generation, algorithms identified through this TLR will be transformed into a publicly available resource
